Unit 4 · Session 7 · SLO 2 — Solved Worksheet

Name: AKARSH MURALI AKARSH MURALI | **Reg. No:** RA2511030010067

Unit – 4 : Session – 7 : SLO – 2 | Execute Parallel Tasks with Process Pools

I. Programming Task

• from multiprocessing import Pool
•
• def cube(x):
• return x ** 3
•
• if __name__ == "__main__":
• with Pool(3) as p:
• print(p.map(cube, [1, 2, 3])) # [1, 8, 27]

II. Explanation

• Pool(3) creates three worker processes; map() sends each number to a worker and collects the cubes.
• The __main__ guard is required so child processes (spawned/forked) do not re-run the pool creation code.
• Output: [1, 8, 27] — computed in parallel across the worker processes.
