Unit 4 · Session 7 · SLO 1 — Solved Worksheet

Name: AKARSH MURALI AKARSH MURALI | **Reg. No:** RA2511030010067

Unit – 4 : Session – 7 : SLO – 1 | Multiprocessing Using IPython

I. Fill in the Blanks

1. The multiprocessing module — it spawns separate OS processes so Python code runs truly in parallel (bypassing the GIL).
2. Pool — a Pool manages a group of worker processes and distributes tasks among them.

II. Multiple Choice

1. [1, 4, 9] — p.map(square, [1, 2, 3]) applies square() to each element across 2 worker processes and returns the results in order.

III. Key Notes

• Pool(n) creates n worker processes; the with block ensures workers are closed and joined.
• map() preserves input order regardless of which process finished first.
